## PLASTICS DRAINAGE AND SEWERAGE SYSTEMS

TECHNICAL / PRODUCT GUIDE

# Hepworth Plastics Drainage and Sewerage Systems

## FLEXIBILITY

P.V.C.u. pipes and fittings are regarded as flexible under the stresses set up by backfill and surcharge loads. Properly installed in a suitable bed and surround, part of this load is transmitted to the side fill which is correspondingly consolidated.

The modulus of elasticity of P.V.C.u. varies from about 400,000 p.s.i. when new to about 200,000 p.s.i. after 50 years.

In the event of unforeseen excess loading which could cause fracture of pipes of rigid materials, the P.V.C.u. pipes merely take on a small, and generally temporary, increase in deformation.

## PRECISION MANUFACTURE

The P.V.C.u. system has been based on the past usage and experience with pressure pipe for gravity purposes. Sewerdrain joints are made with the same precision as pressure pipe there is no need to allow for it in design. Connections at a later date can be done with equal confidence.

Precision joints together with longer pipe lengths reduce the risks of blockage and have a minimal effect on flow.

## LIGHT WEIGHT

Handling costs reduced to a minimum. Easily stored, easily laid with fewer men and less machinery.

## RUGGEDNESS

P.V.C.u. can reduce breakage dramatically because of its higher impact strength. Even pipes which have suffered some damage can be partially saved by removing the damaged section.

## CORROSION RESISTANCE

Normal acid or alkali soil conditions have no adverse effect. Sewerdrain can be used for a wide range of industrial effluents. For more detailed information contact our technical department or consult BS code of practice CP.312, Part 1 : 1973.

## EASILY WORKED

No special tools required and not unkind to the hands.

# Hepworth Plastics Drainage and Sewerage Systems

## EXPERIENCE

P.V.C.u. pipes are a proven part of modern building and civil engineering and pressure pipes up to 24" diameter have for many years been used for gravity drainage schemes in all parts of the United Kingdom. They have been used on many major trunk roads and motorways, often with the original pipe design changed to make the most of the wider ranges of sizes available in P.V.C.u.

The crushing strength requirements of rigid material are not relevant to P.V.C.u. because of its flexibility. The wall thickness/diameter ratio of Sewerdrain has been selected so as to be comparable with class B "Pressure Pipes" to BS 3505. The outside diameters are in accordance with ISO/R161 recommendations.

## PREFERRED METRIC RANGE

Because the SEWERDRAIN system has been designed to use a logical size progression from 110mm to 400mm with a single wall thickness to diameter ratio, a more accurate system using the extra available sizes can be designed, often resulting in considerable cost saving.

## GENERAL INFORMATION

### STANDARD LENGTHS

Pipes are normally available and supplied with integral joints in 6m or 9m lengths, but lengths of 3m can be produced if required. Colour, the metric Sewerdrain system is terracotta coloured. Imperial pipe to BS 3505/BS 3506 is grey.

### FLOW

See Appendix III (Flow Charts), page 35. For the Colebrooke white formula the following co-efficients of friction should be used.

When new 0.003mm.

Mature 0.6mm (the normal accepted value for a mature sewer).

#### NOTE

Whilst it is difficult to claim the use of the lower value for a mature P.V.C.u. sewer it should be noted that because of the long lengths and precision joints, it is difficult to induce roughness by misalignment of joints. Stepping does not occur.

## PHYSICAL PROPERTIES

|                                  |  |
|----------------------------------|--|
| Specific Gravity                 | 1.42   |
| Inflammability                   | Will not support combustion                  |
| Specific Heat                    | 1.00kJ / kg / °C                             |
| Thermal Conductivity             | 0.180 J/m <sup>2</sup> / s / °C/m            |
| Co-efficient of Linear Expansion | 0.06mm/m / °C                                |
| Vicat Softening Point (5kg)      | 79 °C  |
| Impact Strength                  | Complies with <b>EN 1401 - 1,3505</b>        |
| Modulus of Elasticity            | 3000 MN / m <sup>2</sup> at 20 °C            |
| Poisson's Ratio                  | 1 : 3  |
| Tensile Strength                 | In excess of 45 MN / m <sup>2</sup> at 20 °C |
| Elongation at Break              | In excess of 80%                             |

## RELEVANT STANDARDS AND RECOMMENDATIONS

### METRIC

110mm - 160mm pipe and fittings . . . . . EN 1401-1  
 200mm - 400mm pipe and fittings . . . . . EN 1401-1  
 Inspection Chamber . . . . . Agreement Certificate No. 76 / 367

### IMPERIAL

18" - 24" pipe and fittings . . . . . BS 3505 : 1986  
 Rubber rings, rubber to . . . . . BS 2494/EN 681-1

It should be noted that Imperial Pipe to BS 3505 is to inch dimensions as I.S.O. / R / 330 and can only be jointed to Sewerdrain by means of adaptors.

### SPECIFICATION

The most straightforward way to ensure a trouble free system is to SPECIFY SEWERDRAIN.

"P.V.C.u. gravity drainage pipes and fittings shall be SEWERDRAIN as marketed by Hepworth Industrial Plastics Ltd., Padiham, Burnley, Lancs."

"Sewerdrain P.V.C.u. gravity drainage system may be used as an alternative throughout. Flow requirements in the various sections will be provided on request and size reductions in keeping with the manufacturers flow charts will be considered."

## PRODUCT DATA

### PIPES

#### metric

| 315                              | 315.0                    | 7.7                                     | 11.095                   |
| 400                              | 400.0                    | 9.8                                     | 17.889                   |

The above form the present Sewerdrain range.

For some time pipes to BS 3505 and 3506 have been supplied for gravity drainage. These are still available: fittings can be fabricated, but the normal Sewerdrain fittings are not suitable. For your information, we have included their dimensions and weights.

#### Imperial

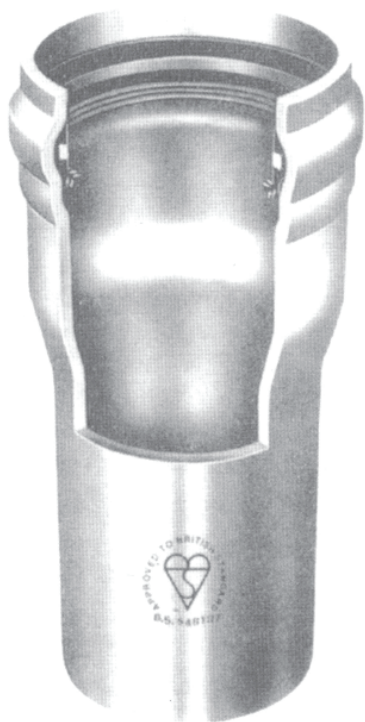

Until our range is extended above 400mm, we recommend the use of 18", 20", 22" and 24" Class B pipes to BS 3506 - 1986

Class B P.V.C.u. to BS 3506 : 1986

# Hepworth Plastics Drainage and Sewerage Systems

## THE SEWERDRAIN LOC-RING INTEGRAL SOCKET

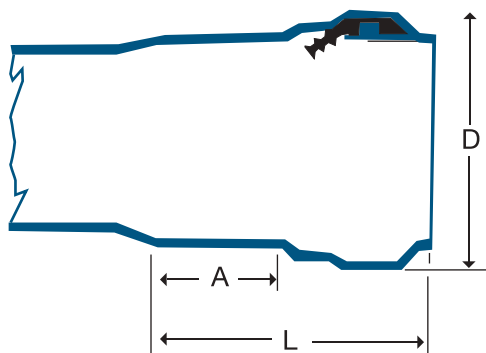

The patented Loc - Ring jointing system has been in widespread use by the Water Industry both in the United Kingdom and the Continent of Europe since 1963.

The socket is manufactured to the highest standard and provides a joint in accordance with EN 1401 - 1

Unique in design, the socket incorporates a triple compression rubber seal complying with British Standard Specification EN 681 - 1 and when jointed offers three-fold hydraulic security under both positive and negative pressure heads.

The rubber sealing gasket is seated and locked into position during manufacture as a safeguard against misuse. The socket is therefore delivered to the customer ready for immediate use and with maximum reliability already built-in.

Assembly of the Loc-Ring Integral Joint requires a minimum of skill and physical effort; it is only necessary to follow the simple jointing instruction. Both above and below ground-level assembly can be carried out with equal simplicity. The joint can be assembled with similar ease when laying under water.

### INTEGRAL JOINT TO EN 1401-1

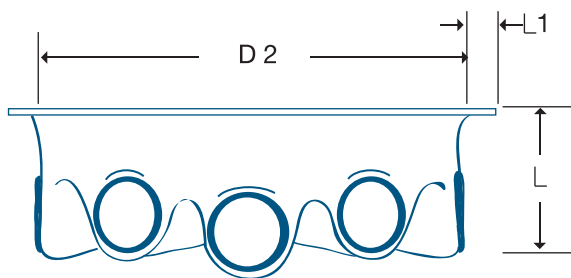

| Pipe O.D. | D   | L   | A   |
|-----------|-----|-----|-----|
| 160mm     | 184 | 101 | 69  |
| 200mm     | 235 | 112 | 75  |
| 250mm     | 290 | 129 | 85  |
| 315mm     | 365 | 151 | 100 |
| 400mm     | 460 | 183 | 120 |

### INTEGRAL JOINT TO BS 3505

| Nom. Dia | D   | L   | A   |
|----------|-----|-----|-----|
| 18"      | 559 | 297 | 153 |
| 20"      | 616 | 313 | 163 |
| 22"      | 670 | 338 | 173 |
| 24"      | 730 | 359 | 184 |

## USE THE SEWERDRAIN INSPECTION CHAMBERS

### INSPECTION CHAMBER BASE

A moulded one-piece unit in corrosion resistant G.R.P. (glass reinforced plastic) forming a quickly installed base for a manhole.

The required connections are made and the base is set in concrete. Flotation should be prevented until the concrete is set. The manhole may then be built up with concrete rings in the normal manner.

| Pipe Dia | D2   | L   | L1 | Weight Kg. |
|----------|------|-----|----|------------|
| 160      | 750  | 300 | 37 | 15         |
| 200      | 1200 | 480 | 37 | 20         |
| 315      | 1200 | 600 | 37 | 24         |

## PLASTIC ROAD GULLEYS

### ROAD GULLEY BODY

CAT. NO. G01A

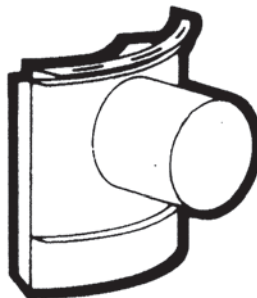

Untrapped body moulded in one piece polypropylene (price includes rubber grommet)

Diameter : 568mm      Depth : 920mm

### ROAD GULLEY TRAP

CAT. NO. G02A

Converts Gully Body (above) into Trapped Road Gully.  
185mm outlet

This improved version of our well proven Polypropylene Road Gully is moulded in two parts ; The Road Gully Body and the Road Gully Trap. Both parts are supplied and priced separately.

The depth of the gully has been increased to 920mm so providing an increase of 28% in capacity over the old 838mm version.

A Rubber Grommet supplied with the Gully Body provides the means by which the trap is sealed to the body. When untrapped gullies are required, the grommet provides the seal between the Gully Body and the connecting pipework.

The requirement to stock both trapped and untrapped gullies has traditionally required a large floor area. This new concept of supplying the trap as a separate item drastically reduces the space necessary for storage since :

- only one type of body is needed to meet either requirement, and
- the gully body can be nested to a high density due to the lack of external trap or outlet.

## PLASTIC ROAD GULLEYS

### SPECIFICATION

For export, shipping costs are materially reduced by the high density of nesting possible. An order for trapped gullies requires no more shipping space than untrapped gullies, since the trap is accommodated within the base of the nesting body.

The Trap comes complete with a 100mm diameter rodding eye fitted with a removable stopper attached to a retaining cord. The position of the internal trap greatly improves the accessibility for rodding.

#### Material

Polypropylene Copolymer having high impact strength even at 0°C.

#### Dimension

## Sitework Instructions

### Transport

Generally, pipes are delivered pre-packed in standard quantities. These pipe bundles are held by nylon straps and timber supports and are usually mechanically handled.

Loose pipes are hand-loaded and care should be taken before loading to check the vehicle's load carrying area for nails and other projections. The pipes must be evenly supported throughout their length, but where this is not possible, timber supports of at least 75 mm bearing width should be placed no more than 2 m apart. When loading socket and spigot pipes, place the sockets at alternate ends of each layer, and allow the sockets to protrude so that the pipes are evenly supported.

The pipes should be loaded so as not to overhang the vehicle by more than one metre. The vehicle should have side supports at centres of no more than 2 m and the inner upright surface should be flat with no sharp edges.

When a mixed load of pipes (i.e. varying diameters) is to be transported, the larger, thicker-walled and thus heavier pipes should be placed at the bottom of the load with the small diameters on top.

Fittings are supplied in cardboard boxes or plastic bags.

The complete load should be correctly secured prior to commencement of the journey.

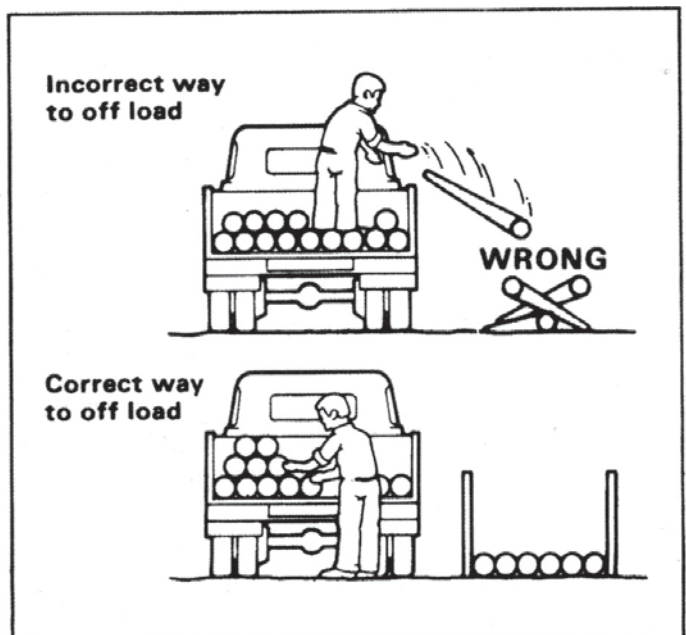

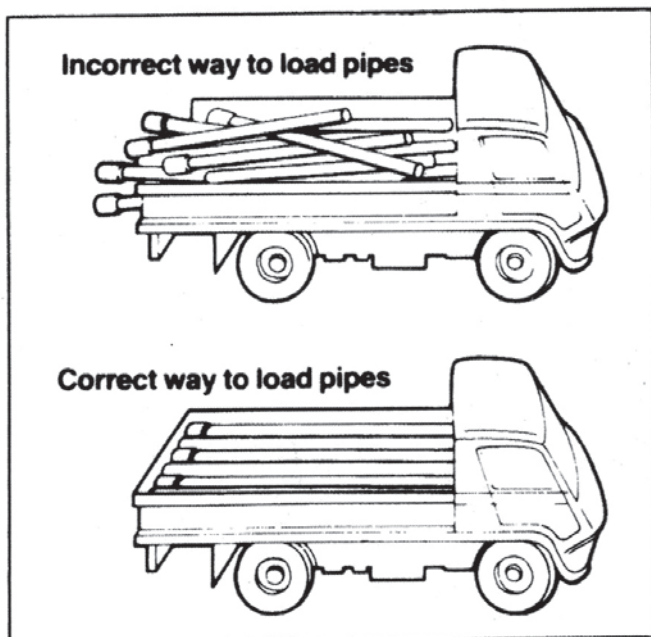

### Handling

One man can easily handle 6 m lengths up to 250 mm diameter, two men can handle up to 400 mm diameter. Mechanical aid will be required for larger sizes and pipe bundles. Because they are so easily handled, care should be taken, especially when pipes are being unloaded for stacking or distribution on site. Pipes should never be thrown from lorries.

When pipes are mechanically lifted, web or rope slings should be used. Metal slings, hooks or chains must not come into contact with the pipes.

When loose pipes have been transported one inside the other, always remove the inner pipe first.

Do not drop or drag pipes.

## Storage

### *Loose Pipes*

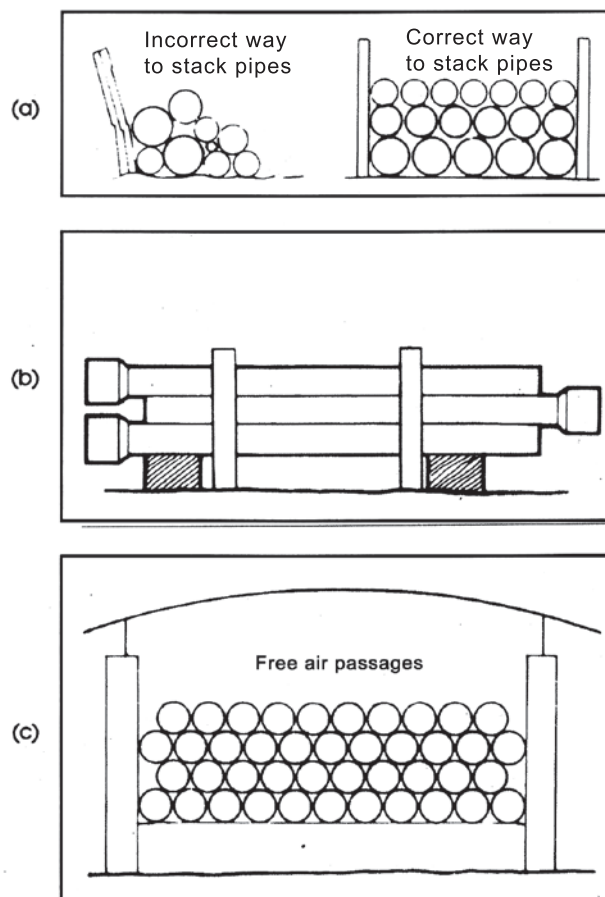

The pipes should be laid on a reasonably flat surface free from large stones or sharp projections, if this is not possible, place the pipes on transverse bearers of at least 75 mm width and spaced at centres not exceeding 1m. Side support should have a minimum bearing width of at least 75 mm and placed at intervals of 1.5 m or less.

Different sizes are best stacked separately, if this is not practical, then stack with the largest pipes at the base (see (a)).

Pipes should not be nested for long periods and stacks should not exceed seven layers or 2 m in height.

When socketed pipes are stacked, the bottom layer of sockets should be prevented from being in direct contact with the ground, either by excavating under the socket, or by use of transverse supports (see (b)).

Alternate layers should have the sockets protruding from and opposite to the previous layer. In warm climates stacks should be limited to 1 m in height and be shaded if practicable (see (c)).

## Product Properties

### Approvals

"Hepworth has a declared company objective to design and manufacture products to the highest standards of quality and technical excellence, to satisfy all appropriate standards, customer requirements and company specifications.

To achieve this objective, the policy of the Board of Directors is to establish, maintain and continually improve through regular review, an effective and efficient quality management system. The quality system provides a framework for control based on the ISO 9000 series of Quality System Standards.

Where appropriate, this policy is endorsed through third party certification such as BAI Kitemark Licence schemes. In certain circumstances, where recognised national/international technical product standards do not exist, or are considered insufficient, third party approval/quality system certification is obtained through British Board of Agreement."

### Physical Properties

## System Design

### Structural Design

The structural performance of PVC-U pipes is assessed as the ability of the pipe to resist deformation under soil and traffic loads. The accepted long-term limit for deformation is 6% of the vertical diameter, and is determined for the particular pipe according to its loading and installation conditions.

### Design Procedure

The soil and traffic loads should be determined from Table 1 for the particular pipe diameter, burial depth and traffic conditions. These values are based on a saturated bulk density of 2000 kg/m<sup>3</sup>, should the site conditions indicate a different soil density then the soil load values can be adjusted on a pro rata basis. The total load (soil load + traffic load) should be determined according to the depth of cover and assumed traffic loading, and the corresponding deformation found by reference to chart number 1.

If the predicted deformation is less than 6 %, then the installation conditions are acceptable.

The design charts are based on the formula

$$\text{Deflection, } \Delta d = \frac{(P_o D + P_t) K_x \times 10^3}{(8 S_i) + (0.061 E')} \quad \text{metres}$$

$$\text{and } D = \frac{\Delta d}{\text{Pipe OD}} \times 100 \quad \%$$

assuming  $P_o$  = soil load (kN/m)

$D_1$  = Deflection lag factor = 1.5

$P_t$  = traffic load (kN/m)

$K_x$  = Bedding factor = 0.103

$S_i$  = Pipe Stiffness = 760N/m<sup>2</sup> (110, 160 dia)

650 N/m<sup>2</sup> (200, 250, 315, 400, 450, 500, 610 dia)

4000 N/m<sup>2</sup> (180, 225, 300 dia Ultra-Rib)

$E'$  = Soil Modulus = 7 x 10<sup>6</sup>N/m<sup>2</sup>

where different values from given above are to be applied, separate calculations will be necessary.

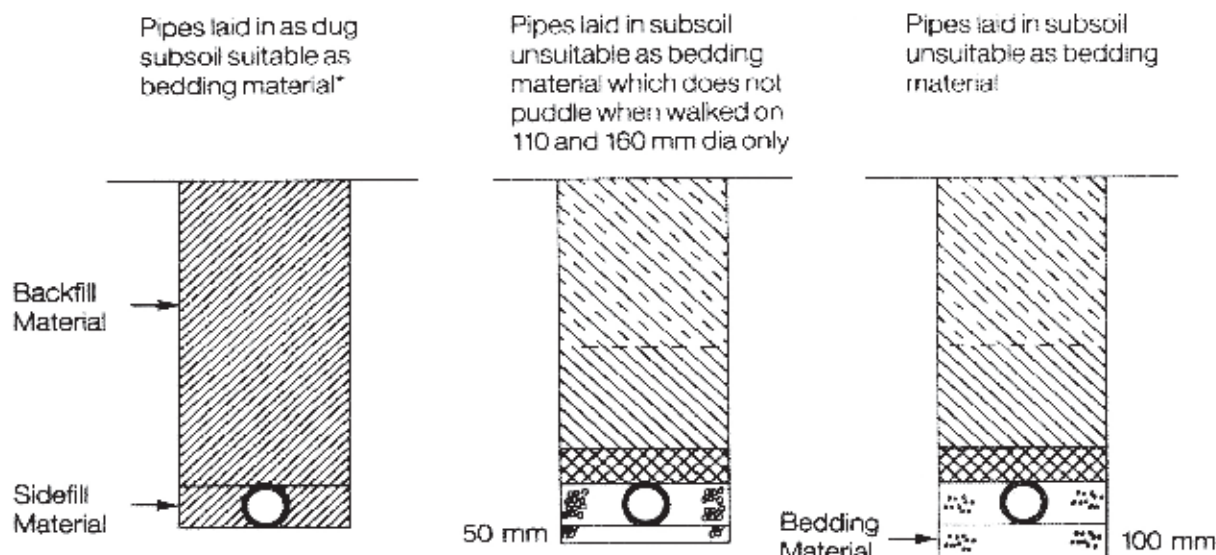

**NB** For pipes with depths of cover less than 0.6 m in fields and 0.9m in carriage ways special protection will be required (see Trench Construction Section).

## Installation Below Ground

### Trench Preparation

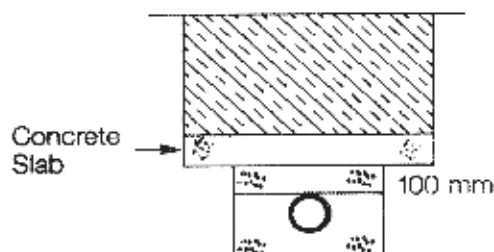

The trench should not be excavated too far in advance of pipe laying and should be backfilled as soon as possible. Trench widths should be as narrow as practicable but not less than the pipe OD plus 300 mm to enable proper compaction of sidefill. Trench sides should be correctly supported.

### Pipes laid at depths greater than 900 mm cover in roads, 600 mm in fields

\*Suitable material – granular material in accordance with BS5955 Part 6 : 1980 Appendix A maximum particle size – 10 mm (110 dia), 14 mm (160 dia), 20 mm (200 dia +)

### Pipes laid at depths less than 900 mm cover in roads, 600 mm in fields

#### Note

Concrete surround.  
Pipes may be protected at shallow depths using a 150 mm thick concrete surround with allowance for flexibility at pipe joints using compressible boards which should be equal in size to the concrete cross section

-  As dug backfill/sidefill maximum particle size 10 mm (110 dia) 14 mm (160 dia) 20 mm (200 dia and over)
-  10 mm single – sized aggregate (complying with BS882)
-  NB – Where backfill above pipe contains stones greater than 40 mm or cover to pipe exceeds 2 m in poor ground extend the bedding material to 100 mm above the pipe crown
-  300 mm backfill free from stones greater than 40 mm (unless granular material extends 100 mm above pipe – see above)
-  As dug backfill
-  Granular material in accordance with BS5955 part 6 1980 : table 2 –  

| Pipe dia (mm) | Material (complying with BS882) (mm)       |
|---------------|--|
| 110           | 10, single sized                           |
| 160           | 10, 14 single sized, 14–5 graded           |
| 200+          | 10, 14, 20 single sized, 14–5, 20–5 graded |

## RECOMMENDED CONSTRUCTION AND BEDDING

The following recommendations should be adopted when laying in the situations listed.

| <i>LOCATION</i>                              | <i>DEPTH TO CROWN OF PIPE</i>                  | <i>BEDDING MATERIAL</i>  | <i>BEDDING DETAIL</i>        |
|--|--|--|------------------------------|
| Fields, Gardens (elsewhere than under roads) | 0.6 metres to 6.0 metres                       | Excavated material with C.F. value not greater than 0.3 or imported granular material  | As Fig. 1, Fig. 2, or Fig. 3 |
| Fields, Gardens (elsewhere than under roads) | Less than 0.6 metres                           | Construction as detailed in Fig. 4   | Fig. 4                       |
| Under Roads                                  | Less than 0.9 metres (below final surface)     | Construction as detailed in Fig. 4   | Fig. 4                       |
| Under Roads                                  | 0.9 metres to 1.2 metres (below final surface) | Excavated material with C.F. value not greater than 0.15 or imported granular material | Fig. 1, Fig. 2 or Fig. 3     |
| Under Roads                                  | 1.2 metres to 6.0 metres (below final surface) | Excavated material with C.F. value not greater than 0.3 or imported granular material  | Fig. 1, Fig. 2 or Fig. 3     |

These requirements apply to trenches in stable soils. In less stable soils, i.e. soft clays, silts or fine sands, it may be desirable to double the thickness of granular bedding and surround given in Figures 1 to 3 and extra care should be taken in compaction.

## FLEXIBILITY

The pipes themselves are flexible. However, where part of the pipe is embedded in concrete (e.g. at a manhole) additional flexibility should be provided by the use of two joints placed close to the concrete face.

The pipes themselves will stand cold bending to a radius of 250 pipe diameters.

## JOINTING

### SPECIAL NOTE

Above 315mm, jointing tackle is available. Never cut a Sewerdrain bend, the curved portion is not designed to form a joint and leakproof jointing may be impossible to achieve. (See jointing instructions.)

## APPENDIX III FLOW CHARTS

The Charts have been designed and prepared by Peter Lamont, M.A., F.I.C.E., F.I.W.E., using Colebrook's well-known Transition Region formula, which he has transposed into the form:

$$V = -2\sqrt{2gdi} \log \left( \frac{k}{3.7d} + \frac{2.51\nu}{d\sqrt{2gdi}} \right)$$

where

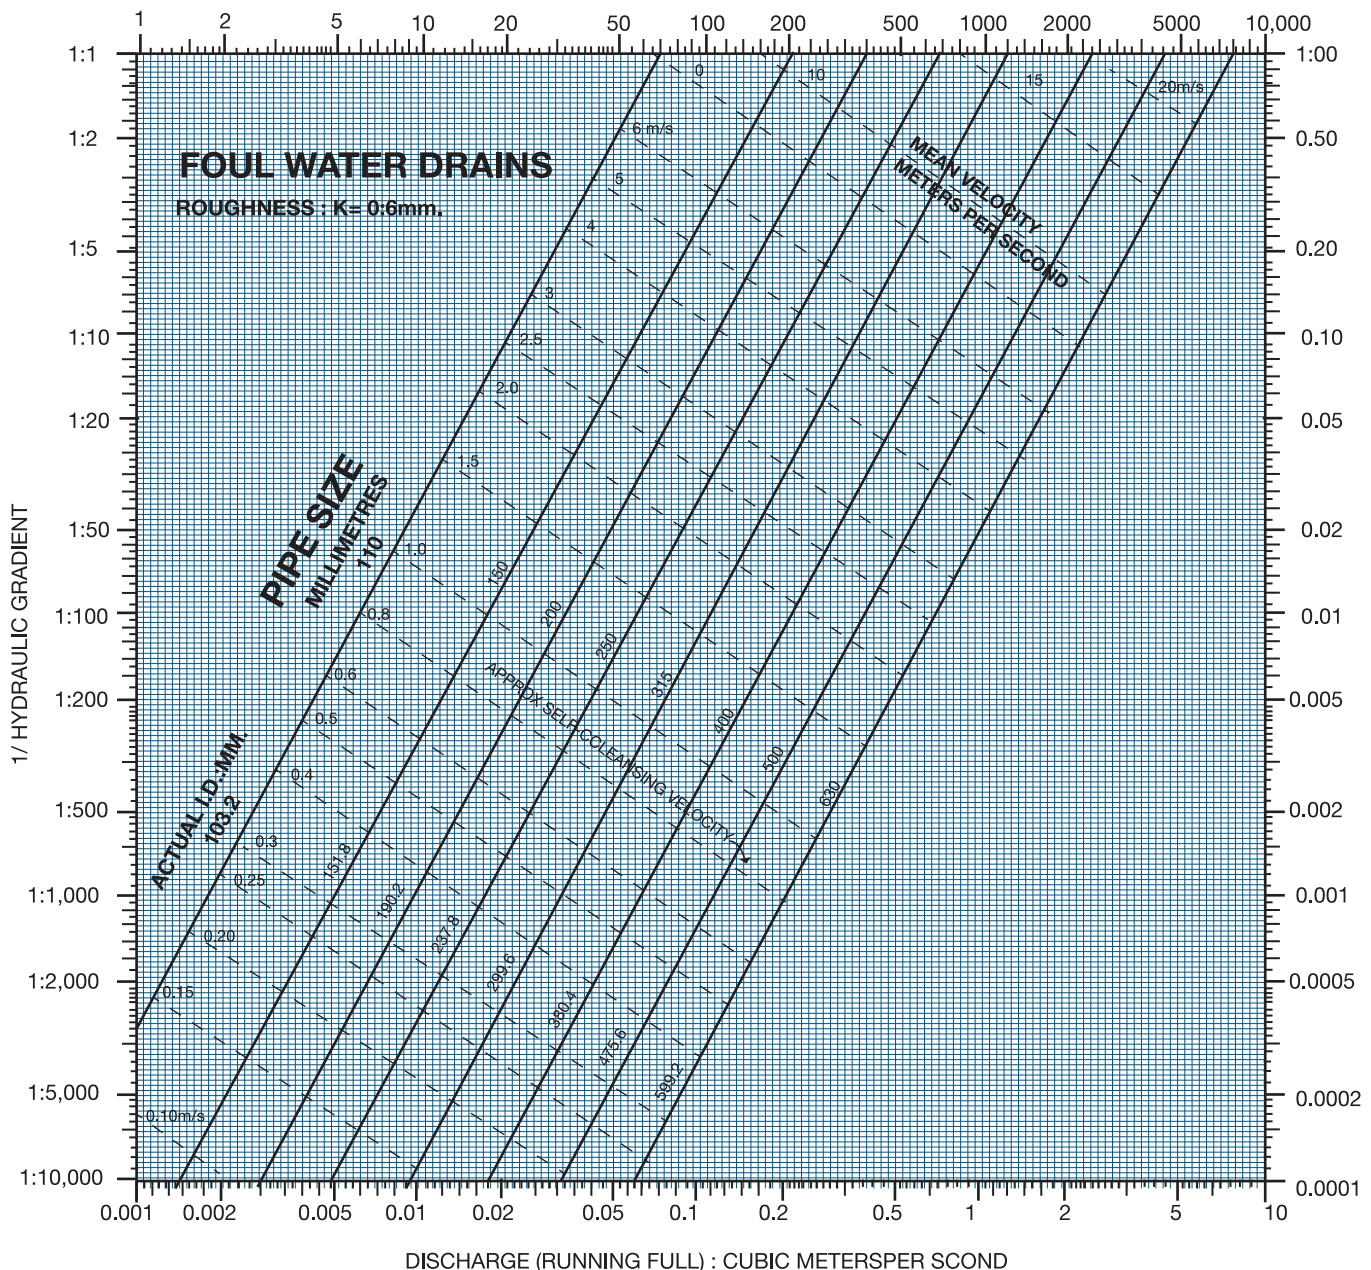

V = velocity  
g = gravitational acceleration  
i = hydraulic gradient (dimensionless)  
 $\nu$  = kinematic viscosity of fluid  
d = internal diameter  
k = a linear measure of effective roughness

Roughness values of 0.6mm and 0.003mm have been assumed for pipes carrying foul water and storm water respectively.

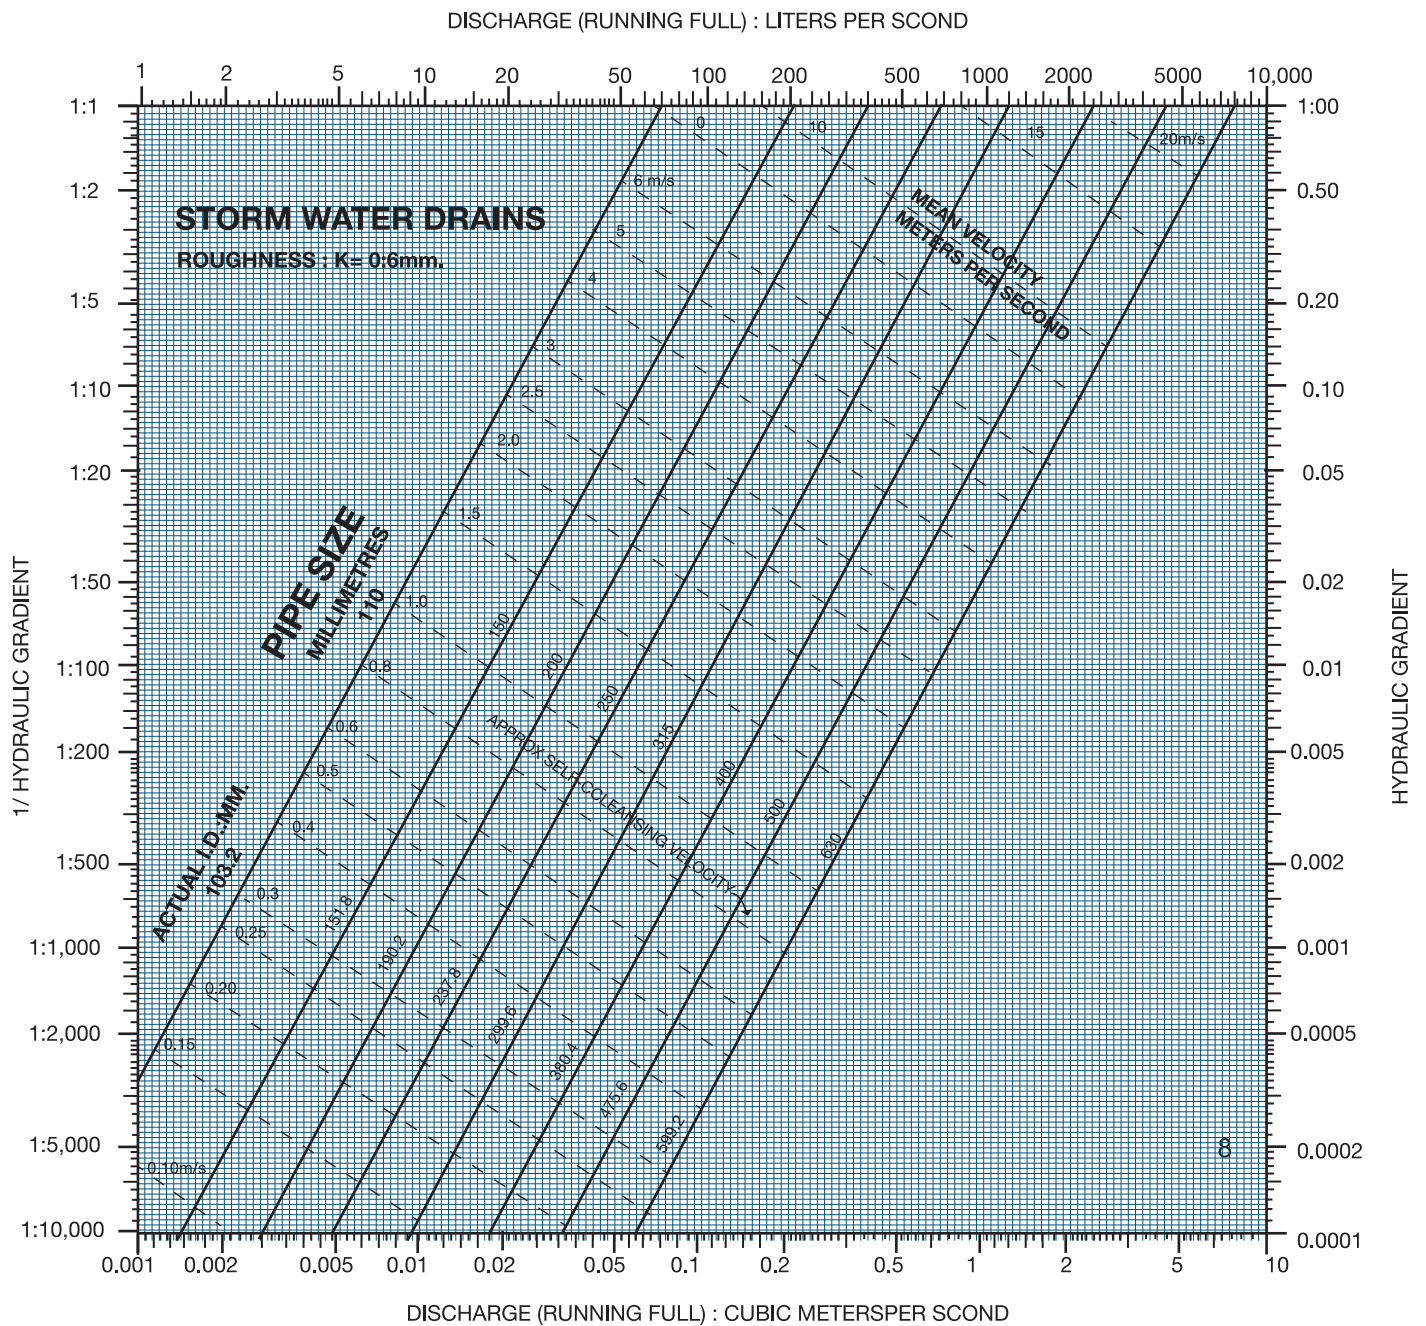

Diagrams have also been prepared for the proportionate discharge and velocity in circular pipes flowing partly full.

These have been based on velocity proportional to (hydraulic radius)<sup>0.667</sup> and may be used in conjunction with the values of discharge and velocity obtained from the Foul Water and Storm Water Diagrams.

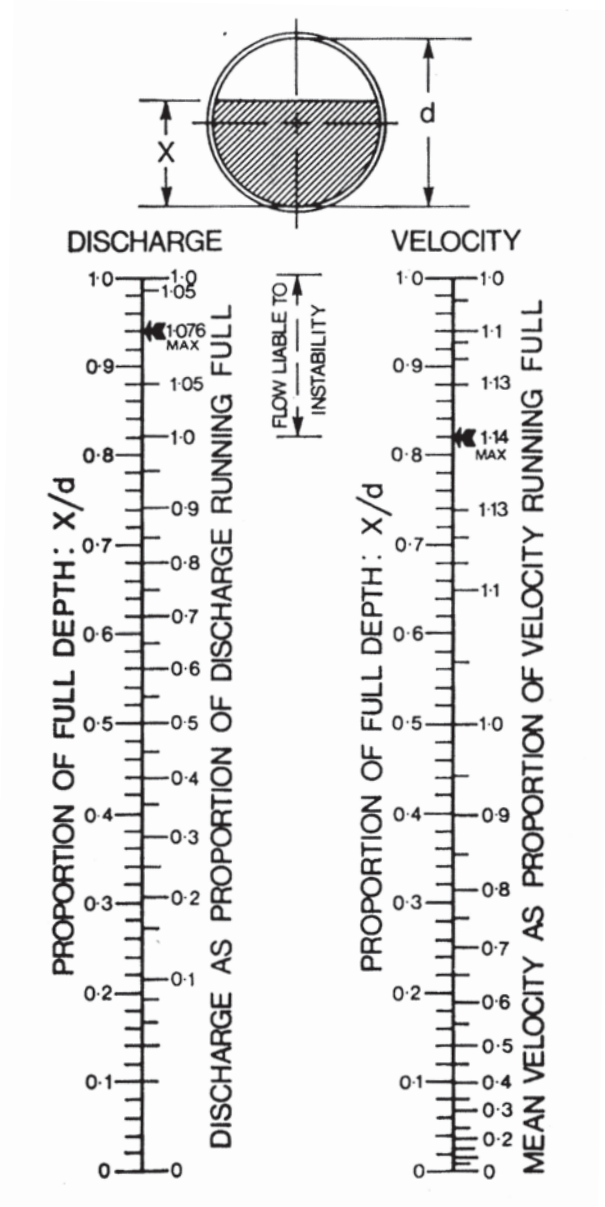

DISCHARGE (RUNNING FULL) : LITERS PER SECOND

# Hepworth Plastics Drainage and Sewerage Systems

## SEWERDRAIN FLOWING PARTLY FULL

### USE OF DIAGRAMS

The line diagrams above (based on  $V$  proportional to  $d^{0.667}$ ) may be used to determine the discharge, velocity and/or depth of flow of **SEWERDRAIN** flowing partly full.

**Example 1:** A 315mm stormwater sewer (actual I.D.=299.6mm) at a gradient of 1:300, has an estimated discharge when full of 85 l/s at a velocity of 1.2 m/s according to the stormwater chart.

Calculate discharge and velocity when running 2/3 full (i.e.  $x/d=0.667$ ).

From discharge diagram: Proportional discharge=0.79.

Hence discharge= $0.79 \times 85=67$  l/s.

From velocity diagram: Proportional velocity=1.108.

Hence velocity= $1.108 \times 1.2=1.3$  m/sec.

**Example 2:** A 500mm foul water sewer (actual I.D.=475.6mm) at a gradient of 1:400 has an estimated discharge when full of 180 l/s at a velocity of 1.05 m/s according to the foul water chart.

Calculate depth of flow and velocity for a discharge of 60 l/s.

Proportional discharge= $60/180=0.333$ .

From discharge diagram: Proportional depth  $x/d=0.4$ .

Hence depth of flow= $0.40 \times 475.6=190$ mm.

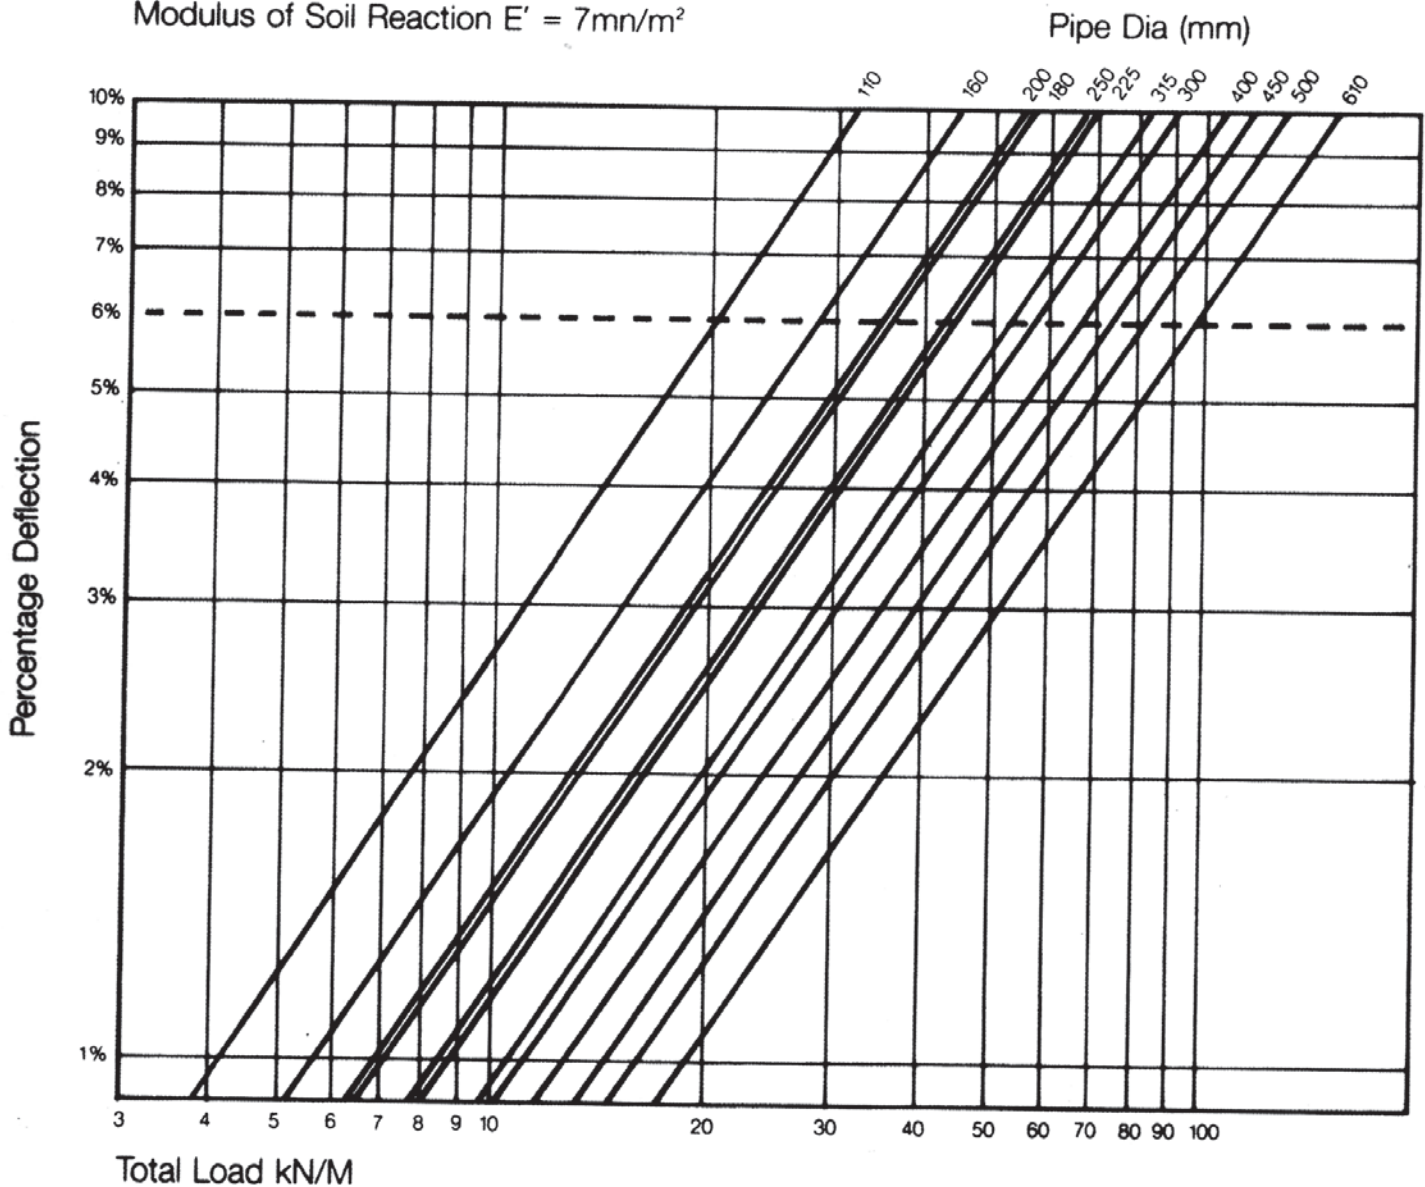

From velocity diagram: Proportional velocity at  $x/d$  0.40=0.90.

Hence velocity= $1.05 \times 0.90=0.95$  m/s.

CHART No. 1

## Predicted Deformation of PVC-U Pipes

Modulus of Soil Reaction  $E' = 7 \text{ mn/m}^2$

NB

If  $E'$  value of the bedding material differs from the above  
then separate calculations will be necessary

## Soil and Traffic Load (kN/m)

| Type of Load                | Pipe diameter (mm) |      |      |      |      |      |      |      |      |      |      |      |
|-----------------------------|--------------------|------|------|------|------|------|------|------|------|------|------|------|
|                             | 110                | 160  | 180* | 200  | 225* | 250  | 300* | 315  | 400  | 450  | 500  | 610  |

\* NB 180 mm, 225 mm and 300 mm are Ultra-Rib internal diameters, the outside diameters are 200 mm, 250 mm and 335 mm respectively.

## APPENDIX I

### TESTS FOR SUITABILITY OF SOIL MATERIAL FOR SURROUNDING SEWERDRAIN

#### PARTICLE SIZE

The ideal is granular (no fines) material 10mm to 20mm. The maximum particle size should generally not exceed 20mm but the presence of an occasional particle between 20mm and 40mm is acceptable, if the total quantity of such particles is only a very small fraction of the whole. If particles larger than 40mm are present, the material should be rejected.

In cases of doubt a representative sample of approximately 2 kg should be weighed and sieved using 20mm and 40mm sieves. If any particles are retained on the 40mm sieve or more than 5% by mass of the sample is retained on the 20mm sieve, the material is unsuitable; unless the whole is sieved before use, thus removing the larger particles.

#### TEST FOR COMPACTION (see British Standards CP 312)

- Apparatus**
- (1) Open cylinder 250mm long and 150mm  $\pm$  6mm internal diameter (160mm Sewerdrain is suitable).
  - (2) Metal ram with striking face 40mm in diameter, weighing 1 to 1.25 kg.
  - (3) Rule.

#### Method

Obtain a representative sample more than sufficient to fill the cylinder (approximately 11 kg). It is important that the moisture content of the sample should not differ materially from that of the main body of material at the time of its use in the trench.

Place the cylinder on a flat firm surface and gently pour the sample material into it, loosely and without tamping. Strike off the top surface level with the top of the cylinder and remove the spilled material. Lift the cylinder clear of its contents and place on a fresh area of surface. Place about one quarter of the contents back in the cylinder and tamp vigorously with the metal ram until no further compaction can be obtained. Repeat with the second quarter, and so on with the third and fourth quarter, tamping the final surface as level as possible.

Measure down from the top of the cylinder to the surface of the compacted material.

This distance (in mm) divided by the height of the cylinder (in mm) is the compaction fraction.

#### RESULTS

| Compaction Fraction | Suitability   |
|---------------------|---|
| 0.15 or less        | Material suitable.  |
| 0.15 to 0.3         | Material suitable but requiring extra care in compaction. Not suitable if the pipe is subject to waterlogged conditions after laying. |
| Over 0.3            | Material unsuitable.  |

## APPENDIX II

### CHEMICAL RESISTANCE

Sewerdrain is suitable for use with most acids, alkalis and aqueous solutions (strong oxidising agents excluded), aliphatic hydro-carbons, plating solutions and mineral oils.

Solvents such as ketones, aldehyds, ethers, esters, aromatic hydro-carbons and halogenated hydrocarbons attack Sewerdrain, even in low concentrations.

For more detailed information contact our Technical Department, or consult British Standard Code of Practice CP 312 Part 1 :1973.

## Pipes and Fittings Jointing

### Plastidrain Polypropylene Couplings 110 and 160mm diameter:

The polypropylene coupling incorporates an elastomeric sealing ring which is compressed by the pipe spigot to form an effective seal. Each joint permits 5° of angular deflection to facilitate installation and allow for ground movement.

Before making the joint ensure that both the pipe end and the sealing ring are clean. Lubricant should be applied to the pipe end which is then inserted into the coupling.

Should the pipe require cutting, the cut end should be chamfered to approximately 15° for half the pipe wall thickness and deburred with a sharp edged tool.

No special provision is necessary to accommodate thermal expansion, this is automatically achieved by the polypropylene coupling.

### Plastidrain and Sewerdrain PVC-U couplings and single sockets :

Before making the joint ensure that both the pipe end and the sealing ring are clean, should cutting be necessary the pipe end should be chamfered as above. Lubricate both the pipe end and the sealing ring in the socket. Ensure that the components to be joined are correctly aligned, then push the spigot fully into the socket. The jointing of larger diameters is generally accomplished by applying leverage to the following socket end using a timber block to prevent damage.

To allow for expansion, mark the spigot at the socket face and then withdraw the spigot by a minimum of 12mm. If the spigot is already marked with the depth of entry, push the spigot home until the mark is just visible.

### Ultra-Rib

The Ultra-Rib sealing ring is placed on the pipe spigot rather than being housed in the socket, hence there is no need to chamfer any cut ends. The spigot and socket should be cleaned, then the sealing ring positioned between the second and third ribs, ensuring that it is seated squarely without twisting. Lubricate the whole of the inside of the socket, align the components to be joined, and “feed” the spigot into the socket. Push the spigot home by applying leverage to the trailing pipe end, using a timber block to prevent damage. Mechanical aids should not be required. The pipe spigot is fully home when the pipe end meets the shoulder of the socket (ie when the fifth rib has entered the socket).

### Trench Backfilling

Hand tamp the backfill fully at the sides of the pipe while tamping lightly over the crown. Hand tamping should continue until a minimum thickness of 300mm has been placed over the pipe.

“As dug” material may then be placed in 300mm layers and mechanically compacted. Dumpers or other vehicles must not be driven along the trench as a means of compaction.

### Testing

All lengths of drains and sewers installed correctly using Hepworth PVC-U drainage systems will be capable of passing the appropriate air or water test specified. The former is usually more convenient but an excessive drop in pressure may be due to a change in temperature, defective apparatus or failure in the pipeline. It is therefore recommended that a water test follows an unsatisfactory air test so that the leakage can be assessed and located (seen (a) and (b) over page).

# Hepworth Plastics Drainage and Sewerage Systems

## (a) **Air test**

- (i) The length of drain or sewer to be tested including any connections should be effectively plugged.
- (ii) Air is pumped into the test length by suitable means (e.g. hand pump) until a pressure of 100mm of water is indicated on a manometer connected to the system.
- (iii) A suitable time should be allowed for stabilisation of air temperature.
- (iv) The air pressure should not fall below 75mm of water during a period of five minutes, without further pumping.

## (b) **Water test**

- (i) Suitable strutted plugs are inserted at the lower end of the drain or sewer and at the head of any connections.
- (ii) A suitable bend together with a vertical length of pipe is fitted at the head of the sewer or drain to provide the necessary test head. The system is then filled with water.
- (iii) A test pressure of 1.50m head above the crown of the pipe is applied at the higher end of the drain or sewer ensuring that the resultant head at the lower end does not exceed 4.0m. Where gradients are steep, it may be necessary to test in sections to avoid exceeding this figure.
- (iv) The sewer or drain under test should be left filled with water for 1-2 hours.
- (v) The loss of water over a period of 30 minutes should be measured, by adding known quantities of water every 10 minutes to maintain the original level in the stand pipe. The loss of water should not exceed the equivalent 1 litre per hour, per linear metre, per metre of nominal diameter. The source of any leakage should be visible and the defective part of the work should be removed and made good.
- (vi) During the water test, strutting precautions should be taken to prevent any movement of the drain or sewer.

## **Installation above ground**

### **Frost:**

PVC-U pipes become less resistant to impact at sub zero temperatures. The pipe should be protected accordingly in exposed conditions. Waterproof lagging should be carried out if the pipes are to stand full under no-flow conditions.

## **Thermal movement**

Thermal expansion and contraction should be allowed for and sufficient freedom of movement allowed for at brackets. Change in length can be calculated from the formula :-

$$\Delta L = \alpha L \Delta T$$

where  $\Delta L$  = change in length (mm)

$\alpha$  = coefficient of liner expansion = 0.05mm/m/°C

$\Delta T$  = change in temperature °C

## **Pipe Support Brackets :**

These should be as wide as practicable with a minimum width of 75mm, with no sharp edges. Bare metal is not advisable, and should have a plastic coating or incorporate a rubber seal for protection.

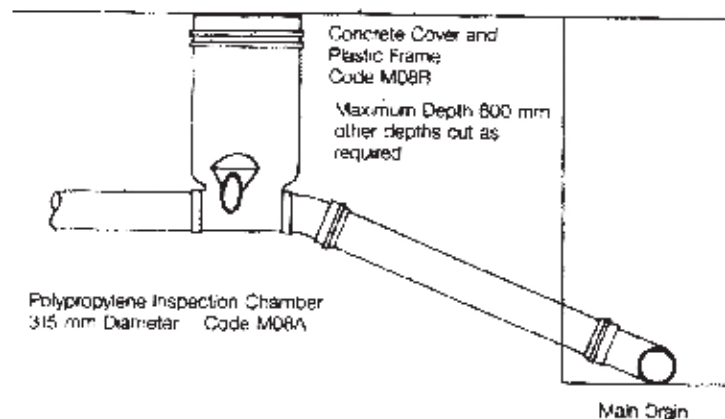

## **Pipe Support Centres :**

These are dependent on the temperature of the contents and the weight. For normal conditions in horizontal pipework, the centres should not exceed :

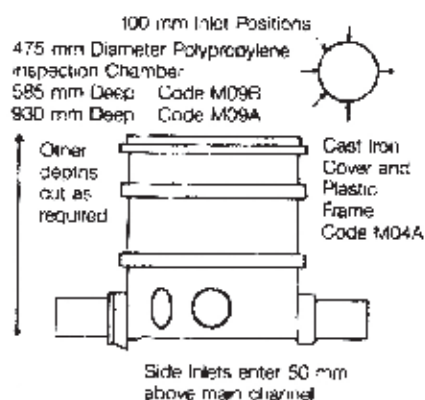

|      |      |         |         |         |      |      |      |          |
|------|------|---------|---------|---------|------|------|------|----------|
| 110  | 160  | 180/200 | 225/250 | 300/315 | 400  | 450  | 500  | 610 (mm) |
| 1.0m | 1.2m | 1.5m    | 1.7m    | 1.8m    | 2.0m | 2.1m | 2.2m | 2.5m     |

For vertical pipework, these distances may be doubled.

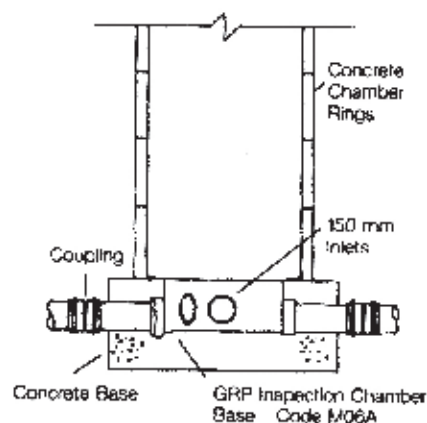

## Application Details

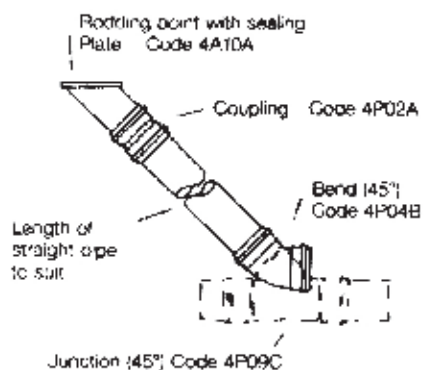

### 119 Polypropylene Inspection Chamber (Positioned off main drain run)

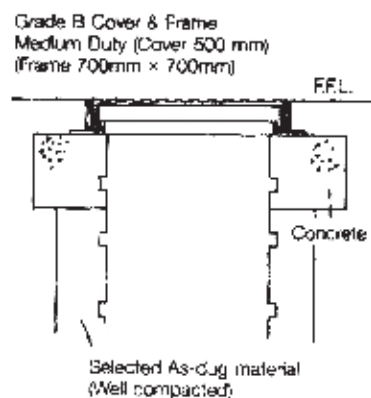

### 150 Polypropylene Inspection Chamber

### 154 GRP Inspection Chamber Base

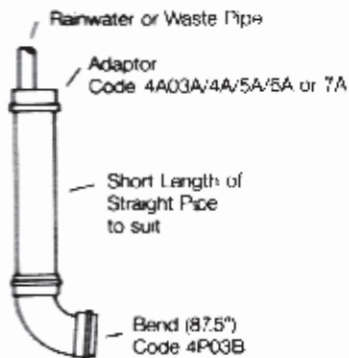

### 121 Rodding Point at head of drain 122 on branch drain

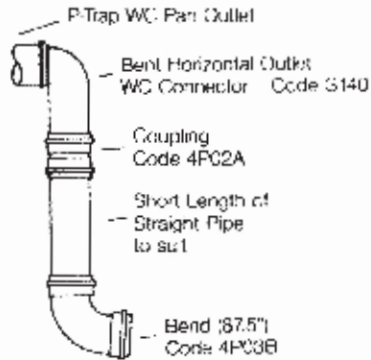

### 152 Chamber sited in Trafficked Area

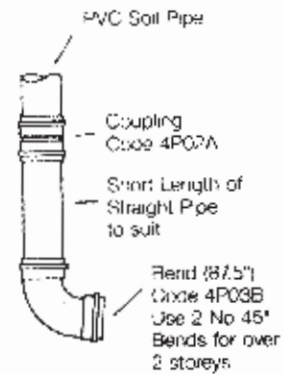

## Application Details

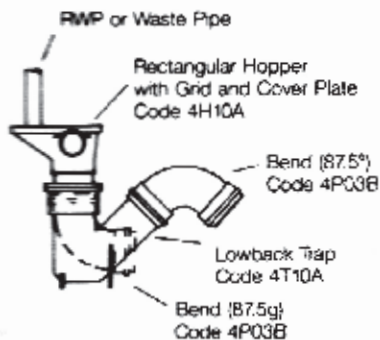

**101 Connection for  
RWP or Waste Pipe**

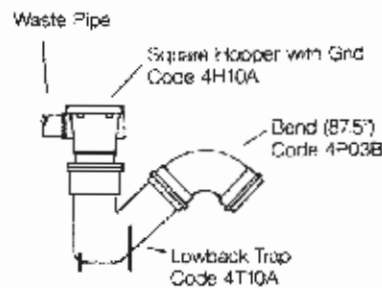

**102 Connection for  
P-Trap WC**

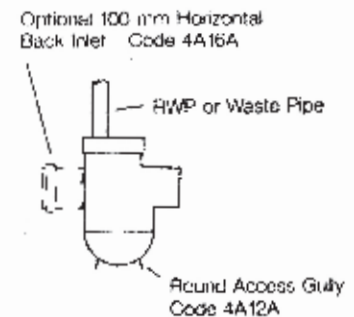

**104 Connection for  
Soil & Vent Pipe**

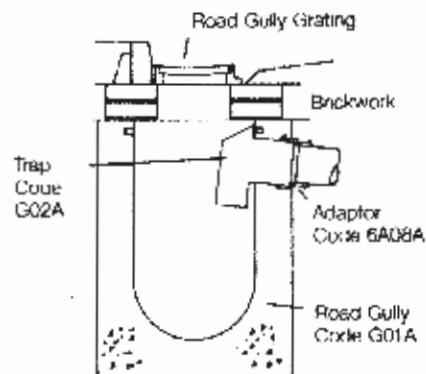

**116 Vertical Inlet  
Trapped Gully  
116A Untrapped Gully**

**113 Horizontal Inlet  
Trapped Gully**

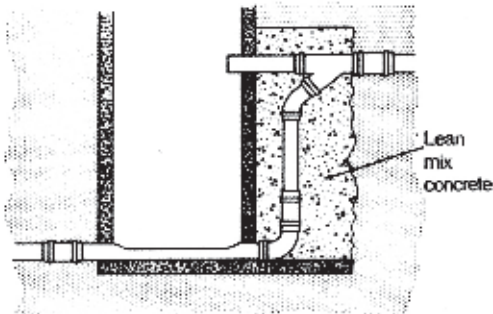

**118 Vertical Inlet  
Access Gully  
118A With Back Inlet**

**140 Polypropylene  
Road Gully**

## CONSTRUCTION OF MANHOLES AND BONDING TO CONCRETE

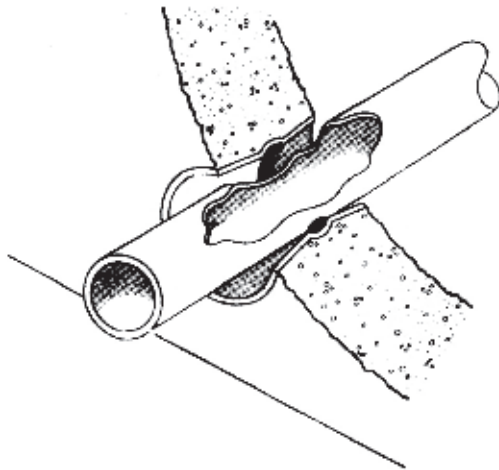

EXTERNAL BACKDROP MANHOLE

Manholes should be constructed in accordance with CP 301:1971. BS Code of Practice Building drainage and/or CP 2005 "Sewerage".

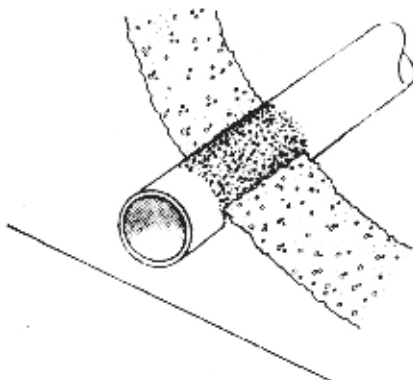

It is useful to consider the following:

This provides a watertight seal, which gives a degree of flexibility, to take care of differential settlement.

### WALL PROTECTION SLEEVE

### BONDING TO CONCRETE

Since u.P.V.C. pipes are extremely smooth the surface needs treatment before a satisfactory bond can be produced. This is best achieved by painting the surface with solvent cement and, whilst it is still wet, sprinkling with *dry* coarse sand or grit. Once the surface has dried, it will bond directly to concrete.

### USEFUL LITERATURE

BS Code of Practice 2005 "Sewerage".

BS Code of Practice 301:1971 "Building Drainage".

BS Code of Practice 312 Parts 1 and 2 1973 "Plastic Pipework".

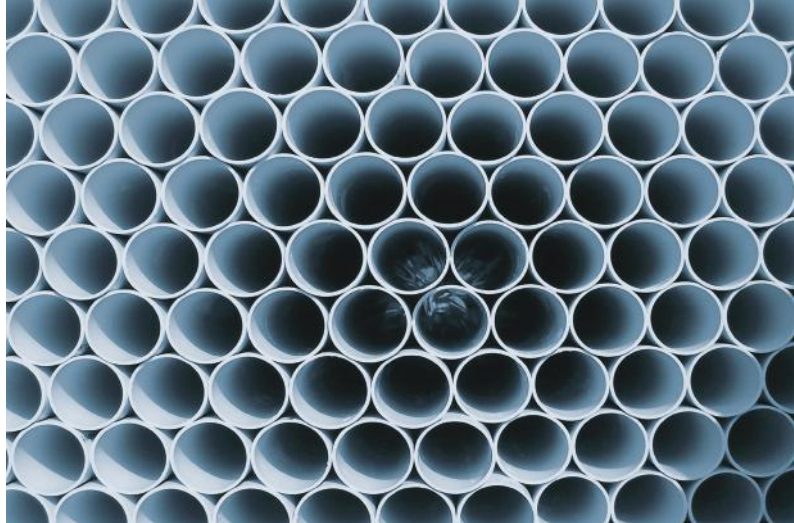

"Note of Guidance on Practical Considerations in the Structural Design and in the Construction of Small Diameter Sewers and Drains" (HMSO: 1967).

## NOTES

This image shows a single sheet of white paper with horizontal ruling lines. The lines are evenly spaced and run across the width of the page. There are no margins, text, or other markings on the paper.
